# **Preface**

The authors thank in particular Dr. Edward A. Lewis for valuable discussions on preparing this paper, SSgt Robert L. Cooley for data preparation, and Mr. Bjarne Ebbesen of the Danish Meteorological Institute for the outstanding operation at Qanaq, Greenland.

Appreciation is also extended to the Danish Commission for Scientific Research in Greenland for allowing these measurements to be conducted and to Jorgen Taagholt and V. Neble Jensen of the Danish Meteorological Institute's Ionospheric Laboratory for their continued cooperation in this program.

# VLF/LF Reflectivity of the Polar Ionosphere 4 September - 31 December 1977

#### 1. INTRODUCTION

This paper provides a summary of high latitude ionospheric reflectivity, as observed by the USAF's high resolution VLF/LF ionosounder operating in northern Greenland. 1, 2 As shown in Figure 1, the transmitter is located at Thule Air Base, Greenland (76° 33'N. Lat., 68° 40'W. Long.), and the receiving site is 106 km north at the Danish Meteorological Institute's Ionospheric Observatory in Qanaq, Greenland (77° 24'N. Lat., 69° 20'W. Long., Geomagnetic Lat. 89° 06'N). The ionosounding transmissions consist of a series of extremely short (approximately 100  $\mu$  sec) VLF pulses, precisely controlled in time, and radiated from a 130 meter vertical antenna. At the receiving site, orthogonal loop antennas are used to separate the two polarization components of the ionospherically reflected skywave signal. One antenna, oriented in the plane of propagation, is used to sense the groundwave and the "parallel" component of the downcoming skywave. The second loop, nulled on the groundwave, senses the "perpendicular" skywave component. The signal from each of the antennas is digitally averaged to improve the signal-to-noise ratio of the individual received waveforms before they are recorded on magnetic tape. An (Received for publication 25 April 1978).

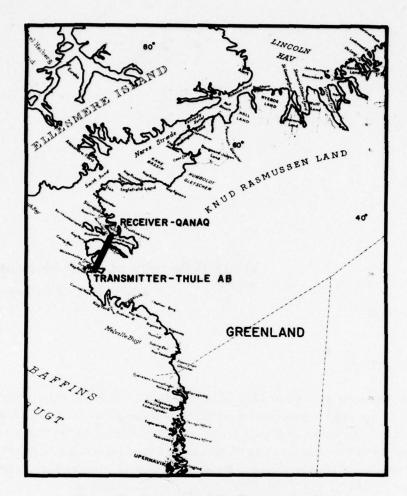

Figure 1. Geometry of the Propagation Path

example of the observed waveforms is given in Figure 2, where the "parallel" waveform (Figure 2a) consists of a groundwave propagated pulse, a quiet interval containing low level, off path groundwave reflections, followed by the first-hop parallel skywave component. The perpendicular waveform is shown in Figure 2b.

Ionospheric reflection parameters are derived by computer (AFGL's CDC 6600) processing of the ground and ionospherically reflected waveforms with allowance made for factors such as ground conductivity and antenna patterns (see Section 4).

Although the data are recorded about once per minute, for this paper the waveforms are averaged into two-hour time blocks with the exception of the three-dimensional waveform presentations (Section 2.2). The resulting information is presented in a weekly format (Figures 3 through 19) as described below.

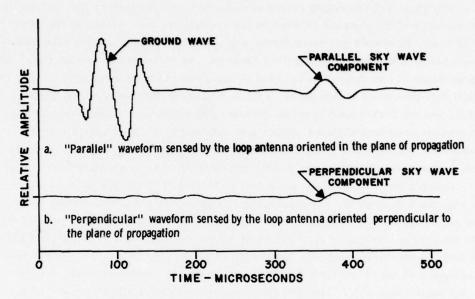

Figure 2. Example of the Observed Waveforms

#### 2. OBSERVED WAVEFORMS

#### 2.1 Weekly Example of Individual Waveforms

In part A of Figures 3 through 19 a set of averaged parallel and perpendicular waveforms is presented for the time block centered near local noon of the indicated day. Each of these waveforms is comprised of 256 digitally averaged points spaced 2 µsec apart. In part B of the figures, the groundwave Fourier amplitudes are shown as a function of frequency. Although the data presented in parts C through L of the figures are generally limited to frequencies in the first, or principal, lobe of the spectrum, information at higher frequencies can be used when sufficient signal-to-noise conditions exist. There is, however, a frequency range around each spectral null where insufficient signal exists for measurements.

## 2.2 Three-Dimensional Waveform Presentation

A three-dimensional display of the recorded | | waveforms covering each weekly period is shown in Part R of each figure and the corresponding \( \Lambda \) waveforms are shown in Part S. For these plots the data has been averaged into fifteen minute time blocks.

#### 3. REFLECTION HEIGHTS

The group mirror height (GMH) of reflection was obtained by determining the group delay of the skywave relative to the groundwave and attributing this time difference, by simple geometry (assuming a sharply bounded mirror-like ionos-phere) to a difference in propagation distance. As discussed in Lewis et al, <sup>1</sup> the group delay can be defined as the rate of change of phase with frequency. For the GMH data presented in this paper, a finite frequency difference of 1.0 kHz was used, and the corresponding phase difference as a function of frequency for the groundwave and both skywave signals was obtained by Fourier analysis of the respective pulses. The GMH calculations took into account ground conductivity (10<sup>-3</sup> mho/meter is assumed), and the corrections of Wait and Howe<sup>3</sup> were applied.

Group mirror heights are plotted as a function of frequency in parts C and D of Figures 3 through 19, as obtained from the parallel and perpendicular waveforms, respectively. The GMH's are also presented as a function of time-of-day for the average frequency of 16.5 kHz in figure parts E and I. The parallel GMH's in part E are shown along with an average reflection height for reference purposes. Each point of the reference height is a weekly average, by time block, for the 7-day period indicated. The corresponding perpendicular GMH's, part I of the figures, are also shown with the weekly average for comparison. Part G gives the average, by time block, for the daily parallel GMH data of part E, and part K gives the corresponding perpendicular GMH averages from the daily data of part I.

#### 4. REFLECTION COEFFICIENTS

Assuming that the ionosphere acts as a "mirror" at the GMH, plane wave reflection coefficients were obtained by comparing the ratio of the skywave Fourier amplitude at a specific frequency to that of the groundwave, taking into account the antenna patterns, wave spreading, earth curvature, ground conductivity, path lenghts, and antenna patterns including ground image effects.

The reflection coefficient ||R|| was obtained from analysis of the parallel sky-wave components and is plotted as a function of frequency in part C of Figures 3 through 19. The ||R|| coefficient for 16 kHz is plotted as a function of time-of-day in part F along with the average of the indicated week for reference purposes. From the perpendicular skywave pulse, the coefficient ||R| was obtained and appears

Wait, J.R., and Howe, H.H. (1956) Amplitude and Phase Curves for Ground-Wave Propagation in the Band 200 Cycles per Second to 500 Kilocycles, Nat. Bur. Stand. U.S. Circ. No. 574.

<sup>4.</sup> Budden, K.G. (1961) Radio Waves in the Ionosphere, p. 85, Cambridge University Press, London.

as a function of frequency in part D. The 16 kHz  $||R\perp|$  is shown along with its reference in part J. Parts H and L present the average, by time block, of the daily ||R|| and  $||R\perp|$  data presented in parts F and J, respectively.

For certain coefficient data points, plotted as asterisks (\*), the reflection coefficient appears without a corresponding GMH. For these particular data, only the skywave-groundwave motion could be obtained as the skywaves were too weak to provide reliable group delay information. The reflection coefficients were therefore estimated using a nominal GMH of 80 km in the calculations. These estimated coefficient values are included in the averages presented in parts H and L, but the assumed heights are not used in the GMH averages shown in parts G and K.

#### 5. SUPPLEMENTARY INFORMATION

For purposes of comparison and interpretation, certain supplementary data are presented. Part M of the figures shows the magnitude of the horizontal component of the polar magnetic field as recorded on a three axis fluxgate magnetometer and part N presents 30-MHz riometer data, an indicator of D-region particle precipitation. These supplementary data were recorded at 30-sec intervals by RADC/EEP at Thule AB; the curves represent the average of 10-minute periods. The solar zenith angle is given in part O of Figures 3 through 19 for the indicated mid-week date.

#### 6. IONOSPHERIC DISTURBANCE DATA

During the period covered by this report the effects of ionospheric disturbances are seen on several occasions in both the ionosounder and the supplementary data. A moderate PCA disturbance occurred beginning on 19 Sept (Day 262). The riometer data indicated a maximum absorption of about 4 dB on the 19th followed by a recovery over the next several days. A second event was recorded on 24 Sept (Day 267), this disturbance produced about 2 dB absorption and lasted 5 days. A third PCA event occurred on 22 Nov (Day 326); this was a minor disturbance producing only 0.75 dB absorption. The VLF/LF ionosounder records show decreases in group heights and reflection coefficients coincident with these disturbances.

The ionosounder data show several other occasions when disturbances occurred which are not seen in the riometer data. These events can be easily seen as lowered group reflection heights during the period 9 - 18 Sept (Days 252 - 261) and on 6 Oct (Day 279) and 13 Oct (Day 286). It is probable that these disturbances resulted from very small particle fluxes below the level to which the riometer is sensitive.

It appears that the VLF/LF ionosounder's response is very sensitive to a small particle flux.

#### 7. ADDITIONAL COMMENTS

Intermittent operation of the transmitter during the period from DAY 250 through DAY 262 is responsible for the missing waveforms and degraded signal-to-noise ratio apparent in the three-dimensional displays. The added noise in the parallel channel during the period from DAY 297 through DAY 337 was caused by a receiver malfunction.

This report is one of a series. 5, 6, 7, 8, 9, 10, 11, 12, 13 Comments and suggestions for improving its usefulness should be addressed to the Propagation Branch (EEP), Electromagnetic Sciences Division, Deputy for Electronic Technology (RADC/EEP), Hanscom AFB, Massachusetts 01731.

## MISSION of Rome Air Development Center

RADC plans and conducts research, exploratory and advanced development programs in command, control, and communications  $(c^3)$  activities, and in the  $c^3$  areas of information sciences and intelligence. The principal technical mission areas are communications, electromagnetic guidance and control, surveillance of ground and aerospace objects, intelligence data collection and handling, information system technology, ionospheric propagation, solid state sciences, microwave physics and electronic reliability, maintainability and compatibility.
